

Compare this with the obtained plots to comment on the characteristics of the spectral approximations of different orders for the different F0 vowels.

The spectral approximations of the LP analysis seems to be quite accurate with increasing period.

Comment on the characteristics of the spectral envelope estimates.

The spectral envelope seems to hit more peaks with increasing periods. This seems to be counter productive and even having a negative impact at some point. For example, for the vowel 'n', LP analysis beyond the period of 8 produces many peaks and decreases accuracy.
